

in RandomUnderSampler instance we put X_{train} and y_{train} number of value that can make the y_{train} groups equally distributed. Takes the majority Class and mix it out with minority classes.

Random Over Sampler

it takes the minority and copy it till it get to the majority Class

SMOTE, is more Robust way (train Set)

Synthetic minority over-Sampling technique

The concept of SMOTE is, where there is a minority it will choose between values of columns and make a new Row, not just copy the entire row for and put it in new Row.

— it can improve the accuracy of your Model

accuracy is not Reliable when there is imbalanced dataset (classes) $\rightarrow$ we use precision, recall, f1-score.
